# meme

A meme (/ˈmiː m/ meem), a neologism coined by Richard Dawkins, is "an idea, behavior, or style that spreads from person to person within a culture". A meme acts as a unit for carrying cultural ideas, symbols, or practices that can be transmitted from one mind to another through writing, speech, gestures, rituals, or other imitable phenomena with a mimicked theme.

# Outline

- Briefly about this ASEAN-IVO workshop series
  - UG students who have not done ANN and RL but attempting FYPs with these components
- What is artificial intelligence?
- A brief history and development of AI.
- An introduction to Reinforcement Learning.
- Development of enabling technology.
- Technology trends.

# What is artificial intelligence?

A Proposal for the  
DARTMOUTH SUMMER RESEARCH PROJECT ON ARTIFICIAL INTELLIGENCE

*June 17 - Aug. 16*

We propose that a 2 month, 10 man study of artificial intelligence be carried out during the summer of 1956 at Dartmouth College in Hanover, New Hampshire. The study is to proceed on the basis of the conjecture that every aspect of learning or any other feature of intelligence can in principle be so precisely described that a machine can be made to simulate it. An attempt will be made to find how to make machines use language, form abstractions and concepts, solve kinds of problems now reserved for humans, and improve themselves. We think that a significant advance can be made in one or more of these problems if a carefully selected group of scientists work on it together for a summer.

DARTMOUTH SUMMER RESEARCH PROJECT ON ARTIFICIAL INTELLIGENCE

*June 17 - Aug. 16*

We propose that a 2 month, 10 man study of artificial intelligence be carried out during the summer of 1956 at Dartmouth College in Hanover, New Hampshire. The study is to proceed on the basis of the conjecture that every aspect of learning or any other feature of intelligence can in principle be so precisely described that a machine can be made to simulate it. An attempt will be made to find how to make machines use language, form abstractions and concepts, solve kinds of problems now reserved for humans, and improve themselves. We think that a significant advance can be made in one or more of these problems if a carefully selected group of scientists work on it together for a summer.

# Challenges in AI

- Crunching numbers
- Infer, deduce
- Muscle skills
- Musical intelligence
- Emotional intelligence
- Spatial intelligence
- Linguistic intelligence
- etc.

# Challenges in AI

- Knowledge representation (KR)
- Compute – quantitative reasoning
- Qualitative reasoning
- Uncertainty
- Changes in beliefs
- Common sense
- Incremental learning

# Deep Learning

A Venn diagram consisting of three concentric circles. The outermost circle is blue and labeled 'ARTIFICIAL INTELLIGENCE'. Inside it is a teal circle labeled 'MACHINE LEARNING'. Inside the teal circle is a smaller orange circle labeled 'DEEP LEARNING'. This visualizes that Deep Learning is a subset of Machine Learning, which is a subset of Artificial Intelligence.

# **ARTIFICIAL INTELLIGENCE**

Programs with the ability to learn and reason like humans

## **MACHINE LEARNING**

Algorithms with the ability to learn without being explicitly programmed

## **DEEP LEARNING**

Subset of machine learning in which artificial neural networks adapt and learn from vast amounts of data

## Why deep learning

How do data science techniques scale with amount of data?

# Notable AI Applications

# Notable AI Applications

Game	Board size	State space	Game tree size
Go	19 x 19	$10^{172}$	$10^{360}$
Chess	8 x 8	$10^{50}$	$10^{123}$
Checkers	8 x 8	$10^{18}$	$10^{54}$

# Notable AI Applications

# Notable AI Applications

# Example: Pancake sorting problem

- ▶ Pancake sorting is the colloquial term for the mathematical problem of sorting a disordered stack of pancakes in order of size when a spatula can be inserted at any point in the stack and used to flip all pancakes above it.
- ▶ In 1979, Bill Gates and Christos Papadimitriou gave an upper bound of  $(5n+5)/3$ . This was improved, thirty years later, to  $18n/11$  by a team of researchers at the University of Texas at Dallas.
- ▶ The minimum number of flips required to sort any stack of  $n$  pancakes has been shown to lie between  $15/14n$  and  $18/11n$  (approximately  $1.07n$  and  $1.64n$ ,) but the exact value is not known.

(Adapt from Wikipedia)

# State Space Search

- ▶ State space search is a process used in the field of computer science, in which successive configurations or states of an instance are considered, with the intention of finding a goal state with a desired property.
- ▶ The typical state space graph is much too large to generate and store in memory. Hence, nodes are generated as they are explored, and typically discarded thereafter.
- ▶ A state space is formally represented as a tuple  $(S, A, B(.,.), eval(.), ,$
- ▶  $S$  is a set of all possible states,  $A$  is a set of possible actions
- ▶  $B: (s(t), a(t)) \rightarrow s(t+1)$ , and  $eval: [s(t-n), \dots, s(t)] \rightarrow \text{reward}$

# State Space Search: A Vacuum-World

- ▶ The world has 2 grids and a vacuum agent lives in this world.

# State Space Search: A Vacuum-World

- ▶ The world has 2 grids and a vacuum agent lives in this world.

- ▶ Each grid may be clean or dirty.

- ▶ **How many possible states are there?**

# State Space Search: A Vacuum-World

- ▶ The world has 2 grids and a vacuum agent lives in this world.

- ▶ Each grid may be clean or dirty.

- ▶ How many possible states are there?

# State Space Search: A Vacuum-World

$S = \{1, 2, 3, 4, 5, 6, 7, 8\}$        $A = \{S, L, R\}$

ex.  $B(1, R) \rightarrow 2$

$\text{eval}([1, 5, 6, 8]) \rightarrow \text{reward signal}$

$\text{eval}([1, 2, 4, 3, 7]) \rightarrow \text{reward signal}$

# State Space Search: Branch and Bound

- ▶ Branching strategy- Example of the two simplest strategies are known as depth-first search and breadth-first search.
- ▶ Depth-first search (also known as branch and backtrack) moves straight down a sequence of branches until a terminal node is reached before backtracking up to the nearest junction.
- ▶ Breadth-first search, on the other hand, enumerates all the branches at one level before moving on to the next level.
- ▶ The bounding process allows us to prune out some partial solutions that cannot lead to optimal solutions. Cutting them and their descendants from the search tree improves search efficiency.

# State Space Search: Branch and Bound

- ▶ Depth-first search – inserts branched states in front of a list
- ▶ Breadth-first search – inserts branched states to the back of a list
- ▶ Uninformed search: the tree is traversed based on the way a node is expanded and how subsequent nodes are explored
- ▶ Informed search: exploits information about the goal node's location in the form of a heuristic function
  - ▶  $f(n) = g(n) + h(n)$
  - ▶ Path cost:  $g(n)$
  - ▶ Heuristic:  $h(n)$

# State Space Search: Lessons Learned

$S = \{1, 2, 3, 4, 5, 6, 7, 8\}$        $A = \{S, L, R\}$

ex.  $B(1, R) \rightarrow 2$

$\text{eval}([1, 5, 6, 8]) \rightarrow \text{reward signal}$        $\text{eval}([1, 2, 4, 3, 7]) \rightarrow \text{reward signal}$

- ▶ When faced with the problem of finding an optimum over a finite set of alternatives.
- ▶ Hooray... we can enumerate all the alternatives and then select the best.
- ▶ However, for anything other than the smallest problems, such an approach is computationally infeasible.
- ▶ It is not a trivial task to knowledge engineer the problem solving approach.

# State Space Search: Adversary Search

Game tree for Tic-Tac-Toe

Courtesy : Artificial Intelligence and Soft Computing, Behavioural and Cognitive Modelling of the Human Brain

- ▶ A two player game
- ▶ Each player will try to maximize one own profit
- ▶ The player x will plan the search by assuming that the player o will play his/her best, hence Max(x), Min(o)

# State Space Search: Adversary Search

- ▶ A two player game where each player try to maximize one own profit.
- ▶ The player x will plan the search by assuming that the player o will play his/her best, hence  $\text{Max}(x)$ ,  $\text{Min}(o)$
- ▶ We think for our opponent, why don't we just observe and exploit that observations?

# Reinforcement Learning

- Reinforcement learning (RL) is an area of machine learning concerned with how software agents ought to take actions in an environment in order to maximize the notion of cumulative reward. Reinforcement learning is one of three basic machine learning paradigms, alongside supervised learning and unsupervised learning.

(Wikipedia)

# Reinforcement Learning

# Reinforcement Learning

- ▶ Reinforcement learning (RL) is one of three basic machine learning paradigms.
- ▶ It learns to behave intelligently from reward signals which implicitly teaching the agent about the environment.
- ▶ The environment is typically formulated as a Markov decision process (MDP)
  - $S$  finite states,
  - $A$  finite actions
  - $T(s,a,s')$  transition probability
  - $R(s,a,s')$  transition reward

# Markov Decision Process

- A Markov decision process is a 5-tuple  $(S, A, T(.,.,.), R(.,.,.), \gamma)$  where
  - $S$  is a finite set of states
  - $A$  is a finite set of actions
  - $T(s, a, s') = P(s(t+1) = s' \mid s(t) = s, a(t) = a)$ 
$$\frac{P(S_{t+1} = s' \mid S_t = s_t, A_t = a_t, S_{t-1} = s_{t-1}, A_{t-1}, \dots, S_0 = s_0)}{P(S_{t+1} = s' \mid S_t = s_t, A_t = a_t)}$$
  - $R(s, a, s')$  is the expected reward after taking action  $a$
  - $\gamma$  in  $[0, 1]$  is a discount factor

# Reinforcement Learning

$s$  is a *state*

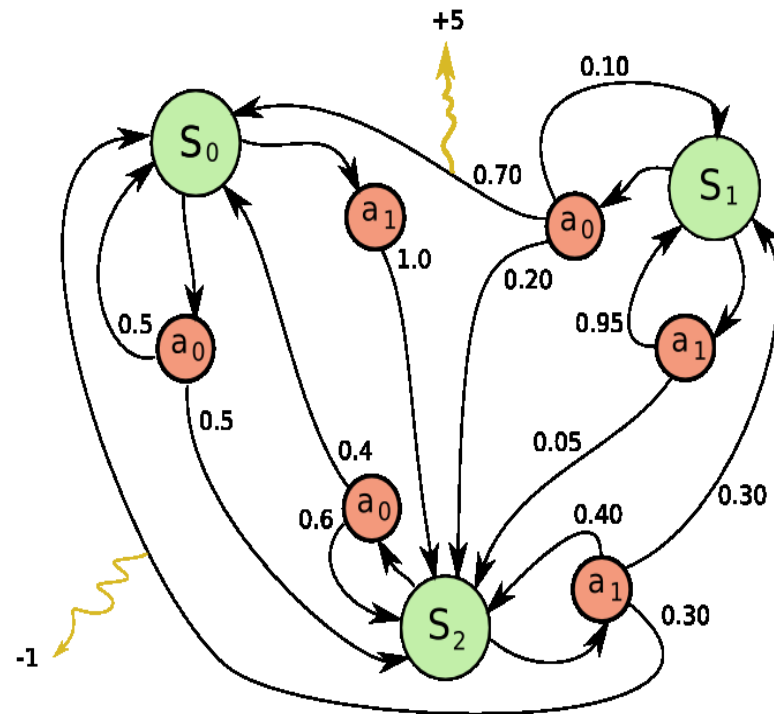

$(s, a, s')$  called a *transition*

$$T(s, a, s') = P(s' | s, a)$$

$$R(s, a, s')$$

# Reinforcement Learning

$$v_{\pi}(s) = \mathbb{E}_{\pi} [R_{t+1} + \gamma v_{\pi}(S_{t+1}) \mid S_t = s]$$

$$q_{\pi}(s, a) = \mathbb{E}_{\pi} [R_{t+1} + \gamma q_{\pi}(S_{t+1}, A_{t+1}) \mid S_t = s, A_t = a]$$

# Bellman Equation - compute $V(s)$

$$\begin{aligned}v_{\pi}(s) &\doteq \mathbb{E}_{\pi}[G_t \mid S_t = s] \\&= \mathbb{E}_{\pi}\left[\sum_{k=0}^{\infty} \gamma^k R_{t+k+1} \mid S_t = s\right] \\&= \mathbb{E}_{\pi}\left[R_{t+1} + \gamma \sum_{k=0}^{\infty} \gamma^k R_{t+k+2} \mid S_t = s\right] \\&= \sum_a \pi(a|s) \sum_{s'} \sum_r p(s', r|s, a) \left[ r + \gamma \mathbb{E}_{\pi}\left[\sum_{k=0}^{\infty} \gamma^k R_{t+k+2} \mid S_{t+1} = s'\right] \right] \\&= \sum_a \pi(a|s) \sum_{s', r} p(s', r|s, a) \left[ r + \gamma v_{\pi}(s') \right], \quad \forall s \in \mathcal{S},\end{aligned}$$

# Reinforcement Learning

$$v_\pi(s) = \sum_{a \in \mathcal{A}} \pi(a|s) q_\pi(s, a)$$

$$q_\pi(s, a) = \mathcal{R}_s^a + \gamma \sum_{s' \in \mathcal{S}} \mathcal{P}_{ss'}^a v_\pi(s')$$

$$q_\pi(s, a) = \mathcal{R}_s^a + \gamma \sum_{s' \in \mathcal{S}} \mathcal{P}_{ss'}^a \sum_{a' \in \mathcal{A}} \pi(a'|s') q_\pi(s', a')$$

# Reinforcement Learning

- ▶ Below are the Bellman equations, and they characterize optimal values.
- ▶  $V^*(s)$  = expected utility starting in  $s$  and acting optimally
- ▶  $Q^*(s,a)$  = expected utility starting out having taken action  $a$  from state  $s$  and (thereafter) acting optimally

$$V^*(s) = \max_a Q^*(s, a)$$

$$Q^*(s, a) = \sum_{s'} T(s, a, s') [R(s, a, s') + \gamma V^*(s')]$$

$$V^*(s) = \max_a \sum_{s'} T(s, a, s') [R(s, a, s') + \gamma V^*(s')]$$

# Reinforcement Learning

# Reinforcement Learning

$$R(s) = -0.01$$

$$R(s) = -0.03$$

$$R(s) = -0.4$$

$$R(s) = -2.0$$
