AIMA book <http://aima.cs.berkeley.edu/instructors.html>

# meme

A meme (/ˈmiːm/ meem), a neologism coined by Richard Dawkins, is "an idea, behavior, or style that spreads from person to person within a culture". A meme acts as a unit for carrying cultural ideas, symbols, or practices that can be transmitted from one mind to another through writing, speech, gestures, rituals, or other imitable phenomena with a mimicked theme.

# Outline

- Overview of the previous session
- Q-learning
- Artificial neural network
- Deep Q-learning
- OpenAI Gym

# Some Historical Background

- **Reinforcement learning (RL)** is an area of machine learning concerned with how software agents ought to take actions in an environment in order to maximize the notion of cumulative reward.
- RL does not assume knowledge of an exact mathematical model of the MDP and it targets large MDPs where exact methods become infeasible.

# Search in a Noisy Landscape

- Traditional search is not designed to handle noise from sensors.
- Reinforcement learning could learn to approximate a better representative of the noisy environment.
- A reinforcement learning system identifies the following elements from reward signals: a policy, a value function, and, optionally, a model of the environment.
- Model is optional since RL could be framed as either a model-based or model-free approach.

# Markov Decision Process

- A Markov decision process is a 5-tuple  $(S, A, T(.,.,.), R(.,.,.), \gamma)$  where
  - $S$  is a finite set of states
  - $A$  is a finite set of actions
  - $T(s, a, s') = P(s(t+1) = s' \mid s(t) = s, a(t) = a)$ 
$$\frac{P(S_{t+1} = s' \mid S_t = s_t, A_t = a_t, S_{t-1} = s_{t-1}, A_{t-1}, \dots, S_0 = s_0)}{P(S_{t+1} = s' \mid S_t = s_t, A_t = a_t)}$$
  - $R(s, a, s')$  is the expected reward after taking action  $a$
  - $\gamma$  in  $[0, 1]$  is a discount factor

# Definitions

## Definition

A *policy*  $\pi$  is a distribution over actions given states,

$$\pi(a|s) = \mathbb{P}[A_t = a \mid S_t = s]$$

- A policy fully defines the behaviour of an agent
- MDP policies depend on the current state (not the history)
- i.e. Policies are *stationary* (time-independent),  
 $A_t \sim \pi(\cdot|S_t), \forall t > 0$

# Definitions

## Definition

The *state-value function*  $v_\pi(s)$  of an MDP is the expected return starting from state  $s$ , and then following policy  $\pi$

$$v_\pi(s) = \mathbb{E}_\pi [G_t \mid S_t = s]$$

## Definition

The *action-value function*  $q_\pi(s, a)$  is the expected return starting from state  $s$ , taking action  $a$ , and then following policy  $\pi$

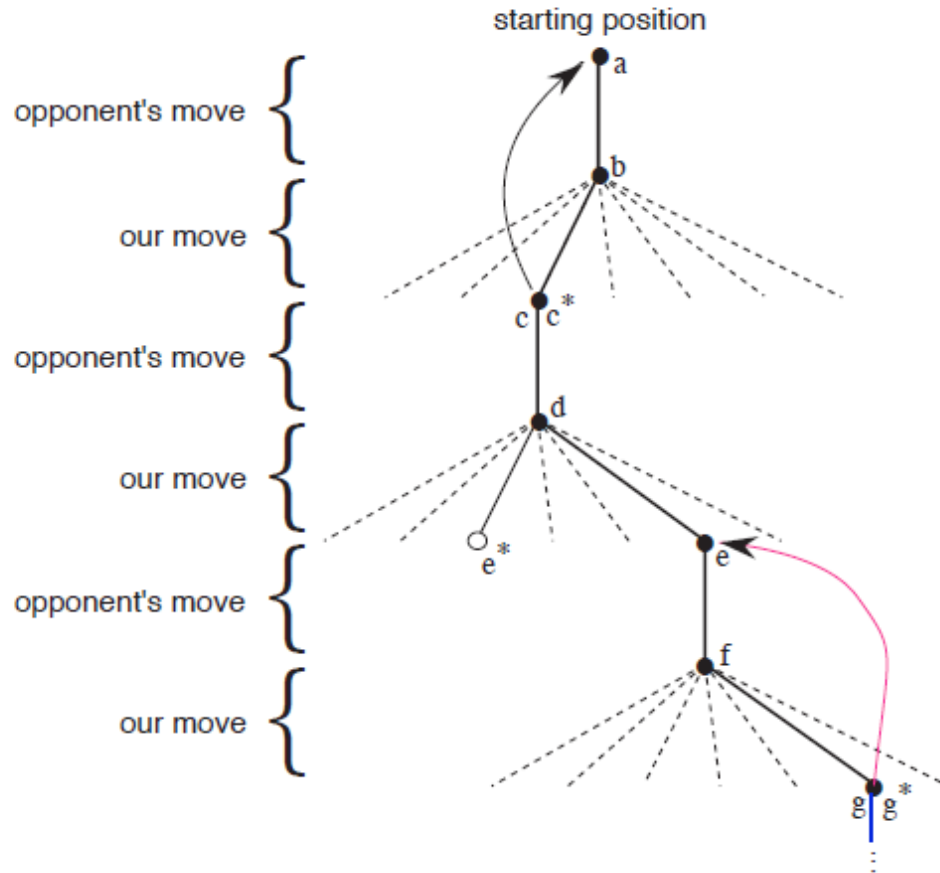

$$q_\pi(s, a) = \mathbb{E}_\pi [G_t \mid S_t = s, A_t = a]$$

# Bellman Equation - compute $V(s)$

$$\begin{aligned}v_{\pi}(s) &\doteq \mathbb{E}_{\pi}[G_t \mid S_t = s] \\&= \mathbb{E}_{\pi}\left[\sum_{k=0}^{\infty} \gamma^k R_{t+k+1} \mid S_t = s\right] \\&= \mathbb{E}_{\pi}\left[R_{t+1} + \gamma \sum_{k=0}^{\infty} \gamma^k R_{t+k+2} \mid S_t = s\right] \\&= \sum_a \pi(a|s) \sum_{s'} \sum_r p(s', r|s, a) \left[ r + \gamma \mathbb{E}_{\pi}\left[\sum_{k=0}^{\infty} \gamma^k R_{t+k+2} \mid S_{t+1} = s'\right] \right] \\&= \sum_a \pi(a|s) \sum_{s', r} p(s', r|s, a) \left[ r + \gamma v_{\pi}(s') \right], \quad \forall s \in \mathcal{S},\end{aligned}$$

# Reinforcement Learning

- Reinforcement learning (RL) is an area of machine learning concerned with how software agents ought to take actions in an environment in order to maximize the notion of cumulative reward. Reinforcement learning is one of three basic machine learning paradigms, alongside supervised learning and unsupervised learning.

(Wikipedia)

# Reinforcement Learning

# Reinforcement Learning

$(s, a, s')$  called a *transition*

$$T(s, a, s') = P(s' | s, a)$$

$$R(s, a, s')$$

# Reinforcement Learning

$$v_{\pi}(s) = \mathbb{E}_{\pi} [R_{t+1} + \gamma v_{\pi}(S_{t+1}) \mid S_t = s]$$

$$q_{\pi}(s, a) = \mathbb{E}_{\pi} [R_{t+1} + \gamma q_{\pi}(S_{t+1}, A_{t+1}) \mid S_t = s, A_t = a]$$

# Reinforcement Learning

$$v_\pi(s) = \sum_{a \in \mathcal{A}} \pi(a|s) q_\pi(s, a)$$

$$q_\pi(s, a) = \mathcal{R}_s^a + \gamma \sum_{s' \in \mathcal{S}} \mathcal{P}_{ss'}^a v_\pi(s')$$

$$q_\pi(s, a) = \mathcal{R}_s^a + \gamma \sum_{s' \in \mathcal{S}} \mathcal{P}_{ss'}^a \sum_{a' \in \mathcal{A}} \pi(a'|s') q_\pi(s', a')$$

# Reinforcement Learning

- ▶ Below are the Bellman equations, and they characterize optimal values.
- ▶  $V^*(s)$  = expected utility starting in  $s$  and acting optimally
- ▶  $Q^*(s,a)$  = expected utility starting out having taken action  $a$  from state  $s$  and (thereafter) acting optimally

$$V^*(s) = \max_a Q^*(s, a)$$

$$Q^*(s, a) = \sum_{s'} T(s, a, s') [R(s, a, s') + \gamma V^*(s')]$$

$$V^*(s) = \max_a \sum_{s'} T(s, a, s') [R(s, a, s') + \gamma V^*(s')]$$

# Tabular RL

Tabular RL approach is a common choice of implementation in various RL learning techniques:

- Temporal different learning (TD)
- Q-learning, and
- SARSA

Actions States	Actions			
	$A_1$	$A_2$	$\dots$	$A_n$
$S_1$	$q_{1,1}$	$q_{1,2}$	$\dots$	$q_{1,n}$
$S_2$	$q_{2,1}$	$q_{2,2}$	$\dots$	$q_{2,n}$
$\vdots$	$\vdots$	$\vdots$	$\ddots$	$\vdots$
$S_m$	$q_{m,1}$	$q_{m,2}$	$\dots$	$q_{m,n}$

# Q Learning

- Q-learning is a model-free reinforcement learning algorithm to learn a policy telling an agent what action to take under what circumstances.
- It does not require a model (hence the connotation "model-free") of the environment, and it can handle problems with stochastic transitions and rewards, without requiring adaptations.
- We will discuss more about the notion of 'Model' in RL in future RL lectures.

# Q Learning

- Q-learning was introduced by Chris Watkins in 1989.
- Watkins was addressing “Learning from delayed rewards”, the title of his PhD thesis.
- The standard Q-learning algorithm (using a Q table) applies only to discrete action and state spaces. Discretization of these values leads to inefficient learning.

# Q-Learning

- Q-Learning: sample-based Q-value iteration

$$Q_{k+1}(s, a) \leftarrow \sum_{s'} T(s, a, s') \left[ R(s, a, s') + \gamma \max_{a'} Q_k(s', a') \right]$$

- Learn  $Q(s,a)$  values as you go
  - Receive a sample  $(s,a,s',r)$
  - Consider your old estimate:  $Q(s, a)$
  - Consider your new sample estimate:

$$sample = R(s, a, s') + \gamma \max_{a'} Q(s', a')$$

- Incorporate the new estimate into a running average:

$$Q(s, a) \leftarrow (1 - \alpha)Q(s, a) + (\alpha) [sample]$$

# Q Learning

$$Q^{new}(s_t, a_t) \leftarrow \underbrace{Q(s_t, a_t)}_{\text{old value}} + \underbrace{\alpha}_{\text{learning rate}} \cdot \underbrace{\left( \underbrace{r_t}_{\text{reward}} + \underbrace{\gamma}_{\text{discount factor}} \cdot \underbrace{\max_a Q(s_{t+1}, a)}_{\text{estimate of optimal future value}} - \underbrace{Q(s_t, a_t)}_{\text{old value}} \right)}_{\text{new value (temporal difference target)}}$$

temporal difference

In 2014 Google DeepMind patented an application of Q-learning to deep learning, titled "deep reinforcement learning" or "deep Q-learning" that can play Atari 2600 games at expert human levels.

# Recap: Q Learning

Algorithm:

Start with  $Q_0(s, a)$  for all  $s, a$ .

Get initial state  $s$

For  $k = 1, 2, \dots$  till convergence

    Sample action  $a$ , get next state  $s'$

    If  $s'$  is terminal:

$$\text{target} = R(s, a, s')$$

    Sample new initial state  $s'$

    else:

$$\text{target} = R(s, a, s') + \gamma \max_{a'} Q_k(s', a')$$

$$Q_{k+1}(s, a) \leftarrow (1 - \alpha)Q_k(s, a) + \alpha [\text{target}]$$

$$s \leftarrow s'$$

# Deep Q Learning (around 2013-2015)

# Deep Q Learning

- The DeepMind system used a deep convolutional neural network, with layers of tiled convolutional filters to mimic the effects of receptive fields.
- **Reinforcement learning is unstable** or divergent when a nonlinear function approximator such as a neural network is used to represent  $Q$ . This instability comes from the correlations present in the sequence of observations, the fact that small updates to  $Q$  may significantly change the policy and the data distribution, and the correlations between  $Q$  and the target values.
- The technique used **experience replay**, a biologically inspired mechanism that uses a random sample of prior actions instead of the most recent action to proceed. This removes correlations in the observation sequence and smooths changes in the data distribution. Iterative updates adjust  $Q$  towards target values that are only periodically updated, further reducing correlations with the target.

# Deep Q Learning

$$Q^{new}(s_t, a_t) \leftarrow \underbrace{Q(s_t, a_t)}_{\text{old value}} + \underbrace{\alpha}_{\text{learning rate}} \cdot \left( \underbrace{r_t}_{\text{reward}} + \underbrace{\gamma}_{\text{discount factor}} \cdot \underbrace{\max_a Q(s_{t+1}, a)}_{\text{estimate of optimal future value}} - \underbrace{Q(s_t, a_t)}_{\text{old value}} \right)$$

$$\underbrace{\left( \underbrace{r_t}_{\text{reward}} + \underbrace{\gamma}_{\text{discount factor}} \cdot \underbrace{\max_a Q(s_{t+1}, a)}_{\text{estimate of optimal future value}} - \underbrace{Q(s_t, a_t)}_{\text{old value}} \right)}_{\text{new value (temporal difference target)}}$$

1. Select an action from possible Q-values actions, select using the epsilon-greedy policy.
2. Perform this action **a** in a state **s** and move to a new state **s'** to receive a reward **r**.
3. Record this transition in our replay buffer as **<s,a,r,s'>**
4. After C iterations, sample data randomly from the replay-buffer and train the ANN using fix target.
5. Update the target Q network
6. Repeat

# Deep Q Learning (breakout)

- The Deepmind paper trained for "a total of 50 million frames (that is, around 38 days of game experience in total)". Note that this paper is published in 2015.
- A Q-Learning Agent learns to perform its task such that the recommended action maximizes the potential future rewards.
- This method is considered an "Off-Policy" method, meaning its Q values are updated assuming that the best action was chosen, even if the best action was not chosen.

# Reinforcement Learning in Gym

# Gym

- Gym is a toolkit for developing and comparing reinforcement learning algorithms.
- Gym makes no assumptions about the structure of your agent, and is compatible with any numerical computation library, such as TensorFlow or Theano.
- The gym library is a collection of test problems — [environments](#) — that you can use to work out your reinforcement learning algorithms

# Available Environments

Gym comes with a diverse suite of environments that range from easy to difficult and involve many different kinds of data. View the full list of environments to get the birds-eye view.

- **Classic control and toy text**
- Algorithmic
- Atari
- 2D and 3D robots

Acrobot-v1  
Swing up a two-link robot.

CartPole-v1  
Balance a pole on a cart.

MountainCar-v0  
Drive up a big hill.

MountainCarContinuous-v0  
Drive up a big hill.

# Gym

The main OpenAI Gym class. It encapsulates an environment with arbitrary behind-the-scenes dynamics. An environment can be partially or fully observed.

The main API methods that users of this class need to know are:

**step**

**reset**

**render**

**close**

**seed**

And set the following attributes:

**action\_space**: The Space object corresponding to valid actions

**observation\_space**: The Space object corresponding to valid observations

**reward\_range**: A tuple corresponding to the min and max possible rewards

Note: a default reward range set to  $[-\text{inf}, +\text{inf}]$  already exists. Set it if you want a narrower range.

The methods are accessed publicly as "step", "reset", etc...

# Environment – Cart Pole

```
import gym
env = gym.make('CartPole-v0')
env.reset()
for _ in range(1000):
    env.render()
    env.step(env.action_space.sample())
env.close()
```

# Environment – Pong

```
import gym
env = gym.make('Pong-v0')
env.reset()
for _ in range(1000):
    env.render()
    env.step(env.action_space.sample())
env.close()
```

# Observations

- Observation (object): an environment - specific object representing your observation of the environment. For example, pixel data from a camera, joint angles and joint velocities of a robot, or the board state in a board game.

## env.step( <action> )

- The environment's step function returns exactly what we need. In fact, step returns four values. These are:
  - observation (object)
  - reward (float)
  - done (Boolean)
  - info (dict)

# Spaces

- We have been sampling random actions from the environment's action space.
- But what actually are those actions? Every environment comes with an `action_space` and an `observation_space`.
- These attributes are of type `Space`, and they describe the format of valid actions and observations.

```
import gym
env = gym.make('CartPole-v0')

print(env.action_space)
#> Discrete(2)

print(env.observation_space)
#> Box(4,)
```

# Agent – Action - Reward

```
import gym
env = gym.make('CartPole-v0')
for i_episode in range(20):
    observation = env.reset()
    for t in range(100):
        env.render()
        print(observation)
        action = env.action_space.sample()
        observation, reward, done, info = env.step(action)
        if done:
            print("Episode finished after {} timesteps".format(t+1))
            break
    env.close()
```

# Q & A
